# L3 - 2.2 - Factor Theorem Lesson

MHF4U

In this section, you will learn how to determine the factors of a polynomial function of degree 3 or greater.

#### Part 1: Remainder Theorem Refresher

**a)** Use the remainder theorem to determine the remainder when  $f(x) = x^3 + 4x^2 + x - 6$  is divided by x + 2

$$f(-2) = (-2)^3 + 4(-2)^2 + (-2) - 6$$

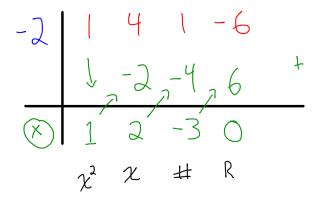

$$f(-2) = -8 + 16 - 2 - 6$$

$$f(-2) = 0$$

**Remainder Theorem:** When a polynomial function P(x) is divided by x - b, the remainder is P(b); and when it is divided by ax - b, the remainder is  $P\left(\frac{b}{a}\right)$ , where a and b are integers, and  $a \neq 0$ .

The remainder when divided by x + 2 is 0. This means that x + 2 is a factor of the dividend.

**b)** Verify your answer to part a) by completing the division using long division or synthetic division.

$$\chi^{3} + 4\chi^{2} + \chi - 6 = (\chi + 2)(\chi^{2} + 2\chi - 3)$$

**Note:** I chose synthetic since it is a linear divisor of the form x - b.

#### **Factor Theorem:**

x - b is a factor of a polynomial P(x) if and only if P(b) = 0. Similarly, ax - b is a factor of P(x) if and only if  $P\left(\frac{b}{a}\right) = 0$ .

**Example 1:** Determine if x - 3 and x + 2 are factors of  $P(x) = x^3 - x^2 - 14x + 24$ 

$$P(3) = (3)^3 - (3)^2 - 14(3) + 24$$

$$P(3) = 27 - 9 - 42 + 24$$

$$P(3) = 0$$

Since the remainder is  $\mathbf{0}$ , x-3 divides evenly into P(x); that means x-3 is a factor of P(x).

$$P(-2) = (-2)^3 - (-2)^2 - 14(-2) + 24$$

$$P(-2) = -8 - 4 + 28 + 24$$

$$P(-2) = 40$$

Since the remainder is not  $\underline{\mathbf{0}}$ , x+2 does not divide evenly into P(x); that means x+2 is not a factor of P(x).

## Part 2: How to determine a factor of a Polynomial With Leading Coefficient 1

You could guess and check values of b that make P(b) = 0 until you find one that works...

Or you can use the Integral Zero Theorem to help.

## **Integral Zero Theorem**

If x - b is a factor of a polynomial function P(x) with leading coefficient 1 and remaining coefficients that are integers, then **b** is a factor of the constant term of P(x).

*Note:* Once one of the factors of a polynomial is found, division is used to determine the other factors.

**Example 2:** Factor  $x^3 + 2x^2 - 5x - 6$  fully.

Let 
$$P(x) = x^3 + 2x^2 - 5x - 6$$

Find a value of b such that P(b) = 0. Based on the factor theorem, if P(b) = 0, then we know that x - b is a factor. We can then divide P(x) by that factor.

The integral zero theorem tells us to test factors of -6.

Test  $\pm 1$ ,  $\pm 2$ ,  $\pm 3$ , *and*  $\pm 6$ . Once one factor is found, you can stop testing and use that factor to divide P(x).

$$P(1) = (1)^3 + 2(1)^2 - 5(1) - 6$$

$$P(1) = 1 + 2 - 5 - 6$$

$$P(1) = -8$$

Since  $\underline{P(1)} \neq \underline{0}$ , we know that  $\underline{x-1}$  is NOT a factor of P(x).

$$P(2) = (2)^3 + 2(2)^2 - 5(2) - 6$$

$$P(2) = 8 + 8 - 10 - 6$$

$$P(2) = 0$$

Since  $\underline{P(2)} = \underline{0}$ , we know that  $\underline{x - 2}$  is a factor of P(x).

You can now use either long division or synthetic division to find the other factors

Method 1: Long division

Method 2: Synthetic Division

**Example 3:** Factor  $x^4 + 3x^3 - 7x^2 - 27x - 18$  completely.

Let 
$$P(x) = x^4 + 3x^3 - 7x^2 - 27x - 18$$

Find a value of b such that P(b) = 0. Based on the factor theorem, if P(b) = 0, then we know that x - b is a factor. We can then divide P(x) by that factor.

The integral zero theorem tells us to test factors of -18.

Test  $\pm 1$ ,  $\pm 2$ ,  $\pm 3$ ,  $\pm 6$ ,  $\pm 9$  and  $\pm 18$ . Once one factor is found, you can stop testing and use that factor to divide P(x).

$$P(1) = (1)^4 + 3(1)^3 - 7(1)^2 - 27(1) - 18$$

$$P(-1) = (-1)^4 + 3(-1)^3 - 7(-1)^2 - 27(-1) - 18$$

$$P(-1) = 0$$

$$P(-1) = 0$$

$$x + 1 \text{ IS a factor of } P(x).$$

Since P(-1) = 0, this tell us that x + 1 is a factor. Use division to determine the other factor.

$$\chi^{4} + 3\chi^{3} - 7\chi^{2} - 27\chi - 18 = (\chi + 1)(\chi^{3} + 2\chi^{2} - 9\chi - 18)$$

We can now further divide  $x^3 + 2x^2 - 9x - 18$  using division again or by factoring by grouping.

#### **Method 1: Division**

Test factors of 
$$-18$$

$$f(-2) = (-2)^3 + 2(-2)^2 - 9(-2) - 18$$

$$f(-2) = 0$$

$$x + 2 \text{ is a factor}$$

$$x + 3x^3 - 7x^2 - 27x - 18 = (x+1)(x+2)(x^2-9)$$

### **Method 2: Factoring by Grouping**

$$f(x) = x^3 + 2x^2 - 9x - 18$$

Group the first 2 terms and the last 2 terms and separate with an addition sign.

$$f(x) = (x^3 + 2x^2) + (-9x - 18)$$

Common factor within each group

$$f(x) = x^2(x+2) - 9(x+2)$$

Factor out the common binomial

$$f(x) = (x+2)(x^2 - 9)$$

Therefore,

$$x^{4} + 3x^{3} - 7x^{2} - 27x - 18 = (x+1)(x^{3} + 2x^{2} - 9x - 18)$$
$$= (x+1)(x+2)(x^{2} - 9)$$
$$= (x+1)(x+2)(x-3)(x+3)$$

#### **Example 4:** Try Factoring by Grouping Again

$$x^4 - 6x^3 + 2x^2 - 12x$$

$$= (x^4 - 6x^3) + (2x^2 - 12x)$$

$$= x^3(x-6) + 2x(x-6)$$

$$=(x-6)(x^3+2x)$$

$$=(x-6)(x)(x^2+2)$$

**Note:** Factoring by grouping does not always work...but when it does, it saves you time!

## Part 3: How to determine a factor of a Polynomial With Leading Coefficient NOT 1

The integral zero theorem can be extended to include polynomials with leading coefficients that are not 1. This extension is known as the rational zero theorem.

#### **Rational Zero Theorem:**

Suppose P(x) is a polynomial function with integer coefficients and  $x = \frac{b}{a}$  is a zero of P(x), where a and b are integers and  $a \ne 0$ . Then,

- b is a factor of the constant term of P(x)
- a is a factor of the leading coefficient of P(x)
- (ax b) is a factor of P(x)

**Example 5:** Factor 
$$P(x) = 3x^3 + 2x^2 - 7x + 2$$

We must start by finding a value of  $\frac{b}{a}$  where  $P\left(\frac{b}{a}\right) = 0$ .

b must be a factor of the constant term. Possible values for b are:  $\pm 1$ ,  $\pm 2$ 

a must be a factor of the leading coefficient. Possible values of a are:  $\pm 1$ ,  $\pm 3$ 

Therefore, possible values for  $\frac{b}{a}$  are:  $\pm 1$ ,  $\pm \frac{1}{3}$ ,  $\pm 2$ ,  $\pm \frac{2}{3}$ 

Test values of  $\frac{b}{a}$  for x in P(x) to find a zero.

$$P(1) = 3(1)^3 + 2(1)^2 - 7(1) + 2 = 0$$

Since  $\underline{P(1)} = 0$ , x - 1 is a factor of P(x). Use division to find the other factors.

$$3x^{3} + 2x^{3} - 7x + 2 = (x-1)(3x^{2} + 5x - 2)$$

$$= (x-1)[3x^{2} + 6x - |x-2]$$

$$= (x-1)[(3x^{2} + 6x) + (-|x-2)]$$

$$= (x-1)[3x(x+2) - |(x+2)]$$

$$= (x-1)(x+2)(3x-1)$$

**Example 6:** Factor  $P(x) = 2x^3 + x^2 - 7x - 6$ 

Possible values for *b* are:  $\pm 1$ ,  $\pm 2$ ,  $\pm 3$ ,  $\pm 6$ 

Possible values of a are:  $\pm 1$ ,  $\pm 2$ 

Therefore, possible values for  $\frac{b}{a}$  are:  $\pm 1$ ,  $\pm \frac{1}{2}$ ,  $\pm 2$ ,  $\pm 3$ ,  $\pm \frac{3}{2}$ ,  $\pm 6$ 

$$f(-1) = 2(-1)^3 + (-1)^2 - 7(-1) - 6 = 0$$

Therefore, x + 1 is a factor of P(x)

### **Part 4: Application Question**

**Example 7:** When  $f(x) = 2x^3 - mx^2 + nx - 2$  is divided by x + 1, the remainder is -12 and x - 2 is a factor. Determine the values of m and n.

Hint: Use the information given to create 2 equations and then use substitution or elimination to solve.

$$f(-1) = 2(-1)^{3} - m(-1)^{2} + n(-1) - 2$$

$$-12 = -2 - m - n - 2$$

$$0 = 16 - 4m + 2n - 2$$

$$-14 = -4m + 2n$$
